# The Impact of Bromide on Chlorine Decay and Disinfection Byproduct Formation

Kyle Shimabuku, PhD, PE  
Tarrah Henrie

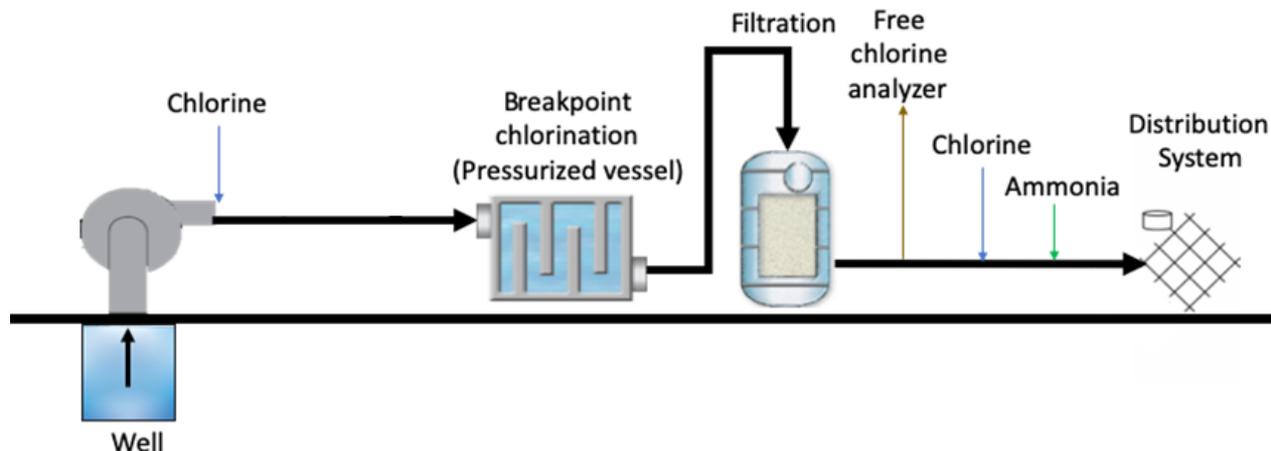

# Motivation

- Chloraminated water system in California fed by groundwater was experiencing blackwater events
  - Wells contained high levels of ammonia and manganese
  - Nitrification and undetectable chlorine levels in the distribution system
  - Insufficient breakpoint chlorination was suspected

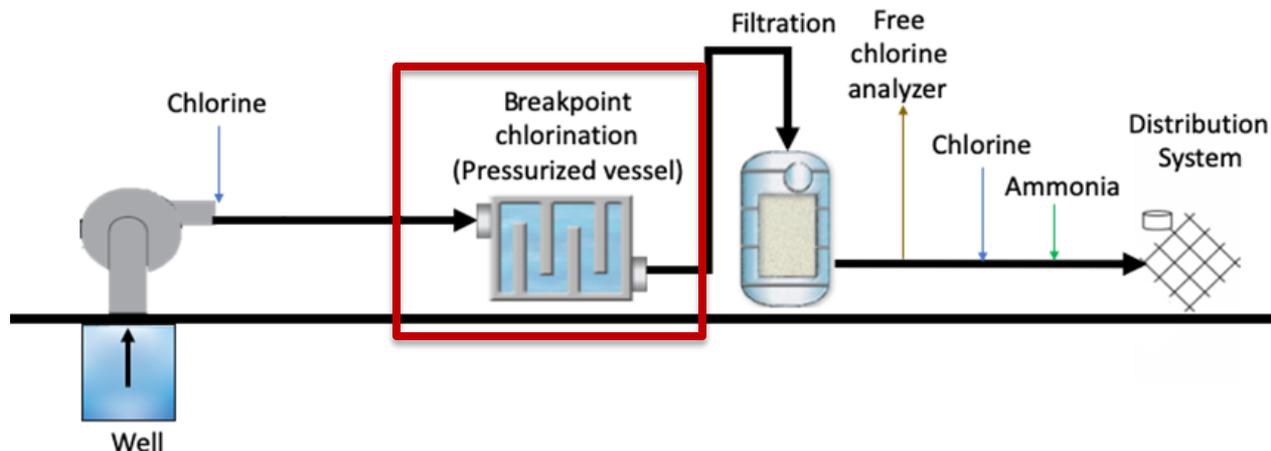

# Goal

- For >10 wells containing ammonia:
  1. Determine optimal breakpoint conditions
    - Chlorine dose
    - Chlorine contact time
  2. Remove manganese with oxidation and filtration
  3. Ensure in simulated distribution system testing
    - Total chlorine residual  $\geq 1.5$  mg/L
    - TTHMs and HAA5s below 60 and 54  $\mu\text{g/L}$ , respectively

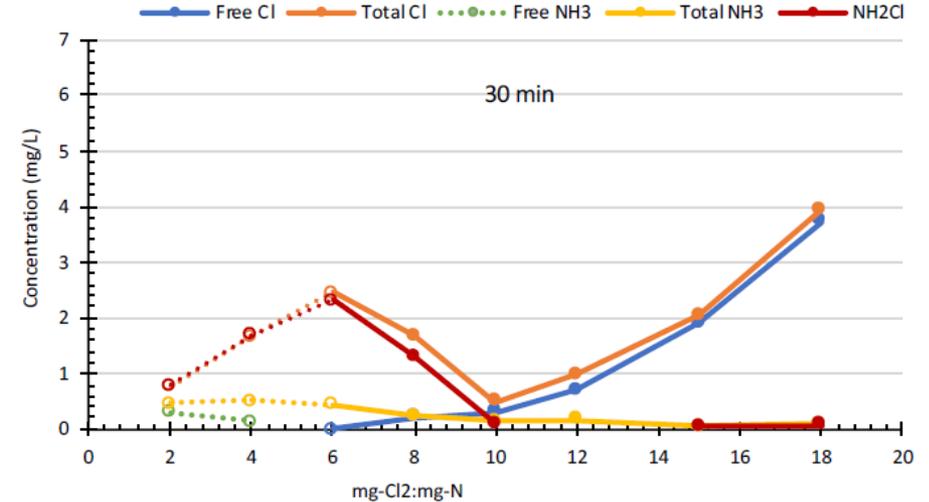

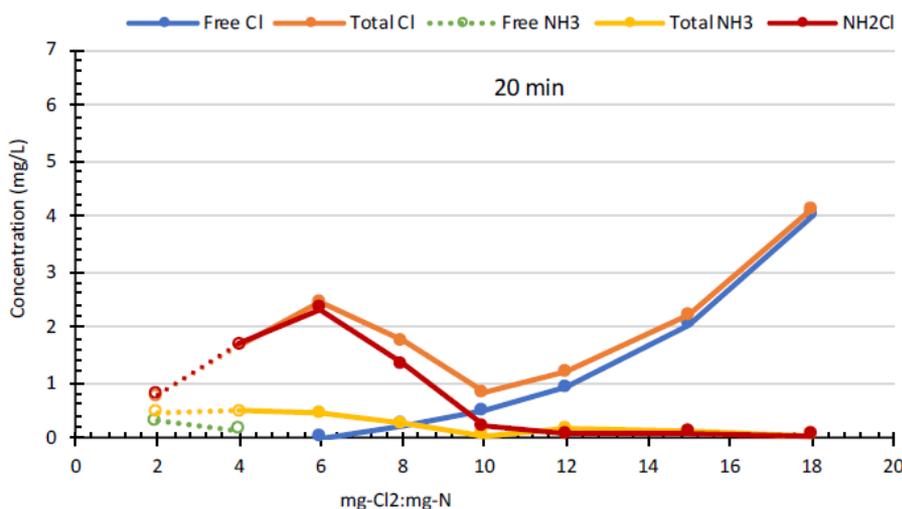

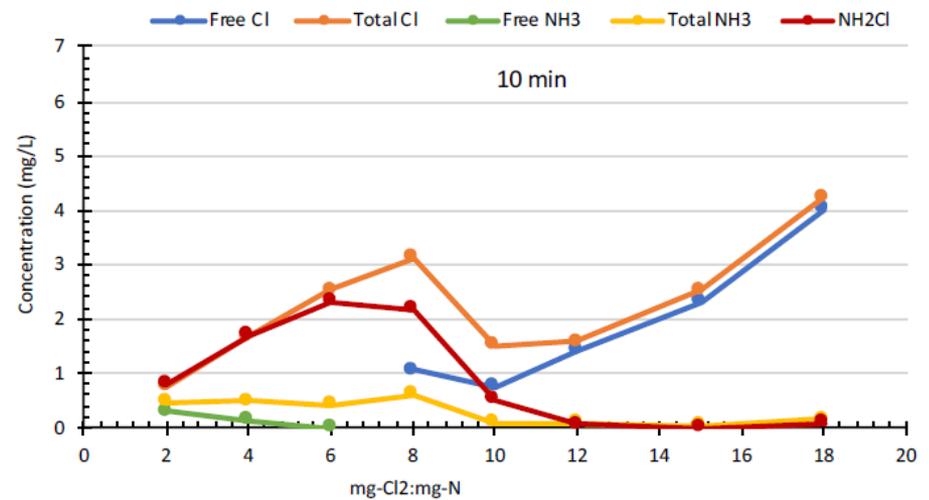

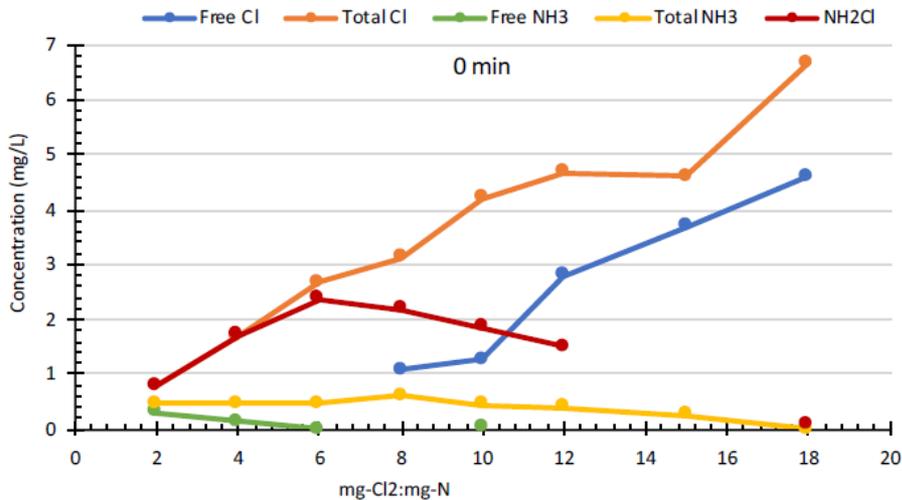

# Bench-scale testing approach

- Study focused on breakpoint chlorination as existing contact times were insufficient
- Testing involved:
  - Adding chlorine at increasing  $\text{Cl}_2:\text{NH}_3$  ratios (e.g., from 2:1, 4:1, 6:1 etc.)
  - Measure Total  $\text{Cl}_2$ , Free  $\text{Cl}_2$ , Total  $\text{NH}_3$ , Free  $\text{NH}_3$ , and  $\text{NH}_2\text{Cl}$  using a Hach SL-1000 every 10 minutes
  - Target complete  $\text{NH}_3$  removal, a  $>2.5$  mg/L free chlorine residual, and free and total Cl within  $\pm 10\%$

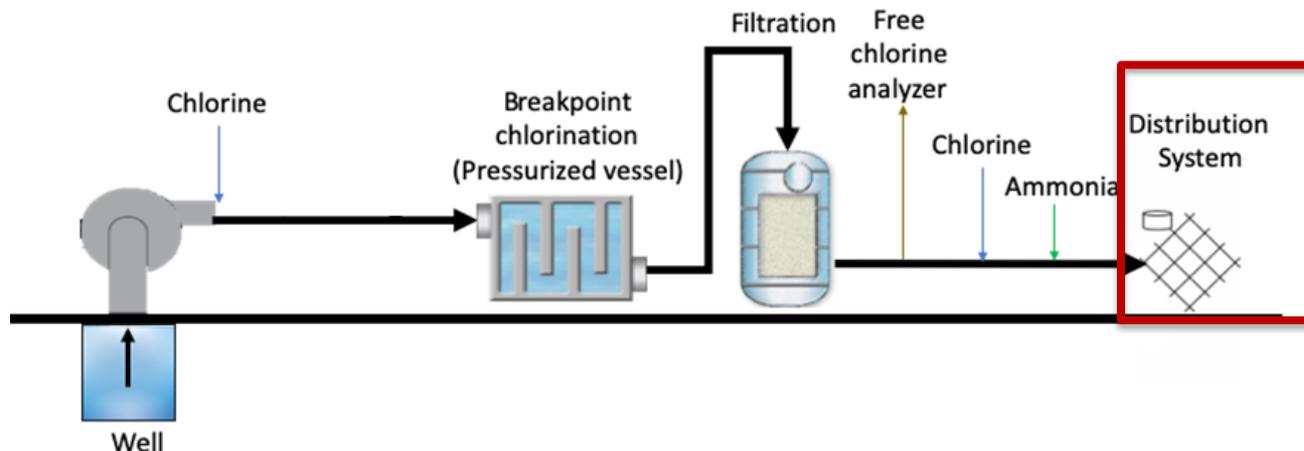

# Example breakpoint curves

- 10-20 minutes and >14:1 Cl<sub>2</sub>:NH<sub>3</sub> appears to be sufficient
- Anticipated breakpoint testing results were found

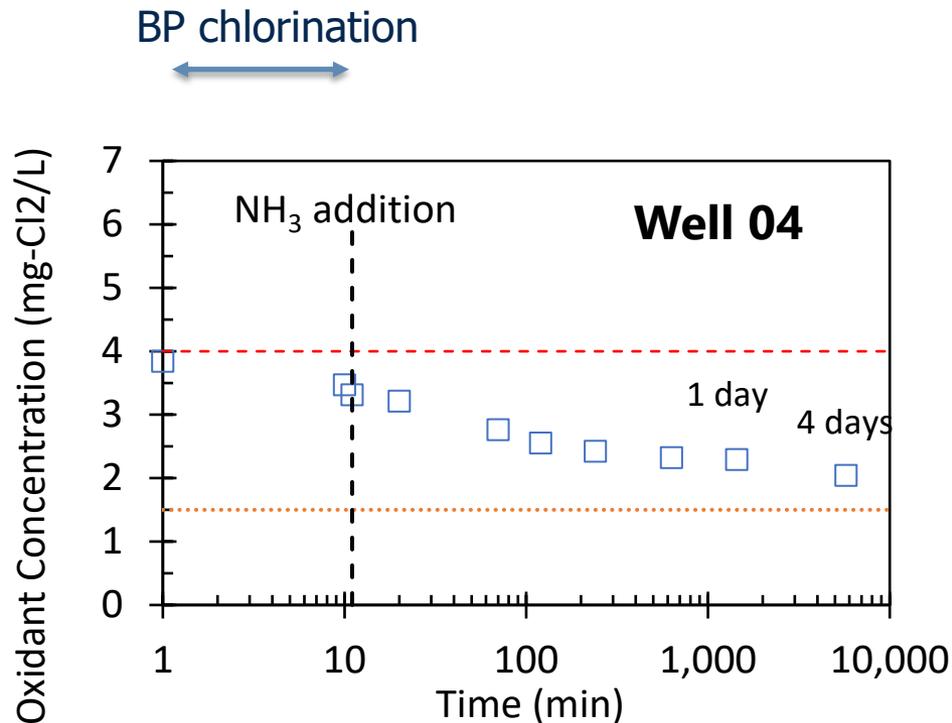

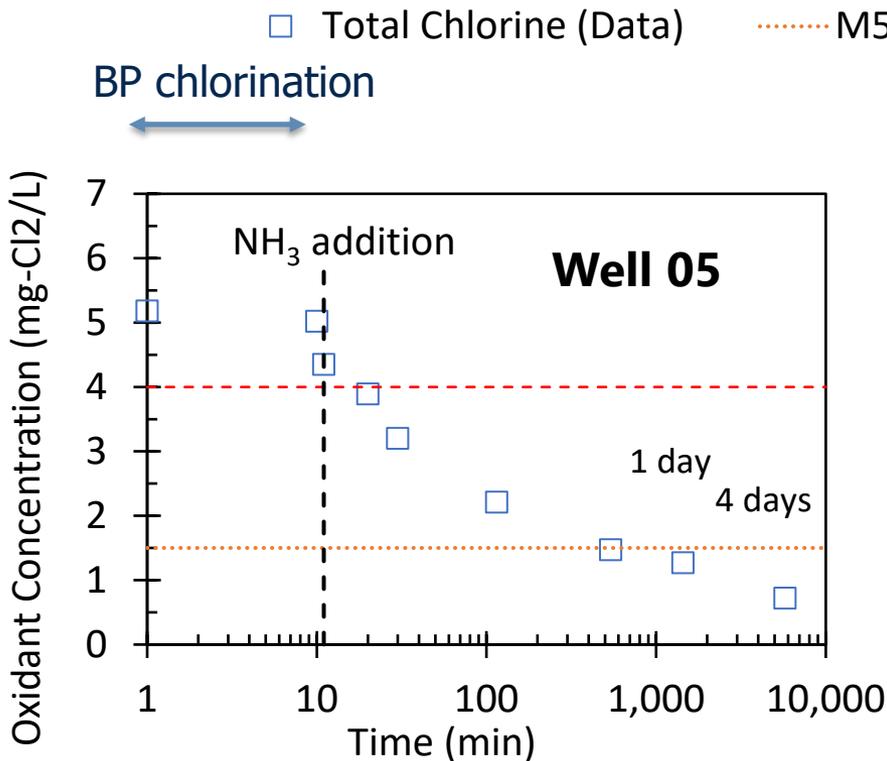

# Simulated Distribution System (SDS) testing

- Dose ammonia to target a  $\geq 4.7:1$   $\text{Cl}_2:\text{NH}_3$  ratio after breakpoint chlorination
- Filter chloraminated samples through  $0.45\ \mu\text{m}$  filters
- Measure relevant constituents field parameters before and after ammonia addition
- Sample after filtration for TTHMs and HAA5s
- Store in headspace free amber bottles in the dark
- Sample at 18 to 24 hours and 4 to 5 days

# SDS testing results

- Of the 12 wells tested, only one well, “Well 05”, could not satisfy total chlorine goal
  - Also had highest levels of DBPs
  - “Well 04” did not show same issues (even though it was only a few hundred feet away)

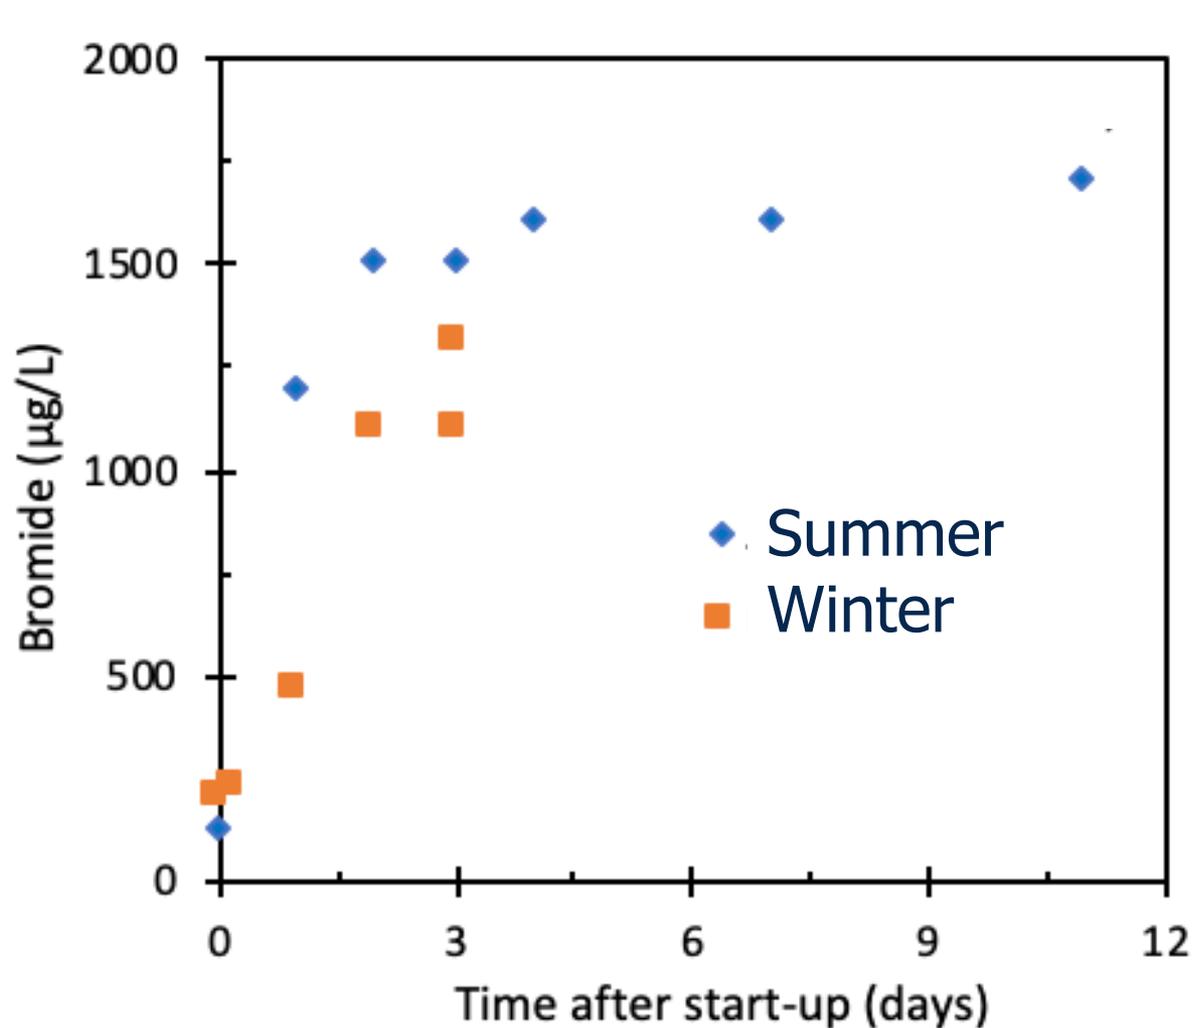

# Raw water quality

- Water quality was largely similar in wells except of bromide

Parameter	Well 04	Well 05
Alkalinity (mg-CaCO <sub>3</sub> /L)	177	150
Ammonia (mg-N/L)	0.12	0.26
Bromide (µg/L)	530	1,700
Chloride (mg/L)	73	240
DO (mg/L)	0.2	0.5
pH	7.9	8
Total Manganese (mg/L)	0.040	0.087
TOC (mg/L)	0.5	1.0
UV <sub>254</sub> (cm <sup>-1</sup> )	0.008	0.015
SUVA (L/mg-C/m)	1.6	1.5

# Raw water quality

- Variability in bromide concentration after well start-up also made diagnosing the problem difficult

# Cause of "Total Cl" decay in Well 05

- High bromide in Well 05 is likely the cause of observed total Cl decay

- Multiple bromamines (e.g.,  $\text{NHBr}_2$ ) and bromochloramine ( $\text{NHBrCl}$ ) can also form which are less stable than  $\text{NH}_2\text{Cl}$

## Bromamines formation and decomposition

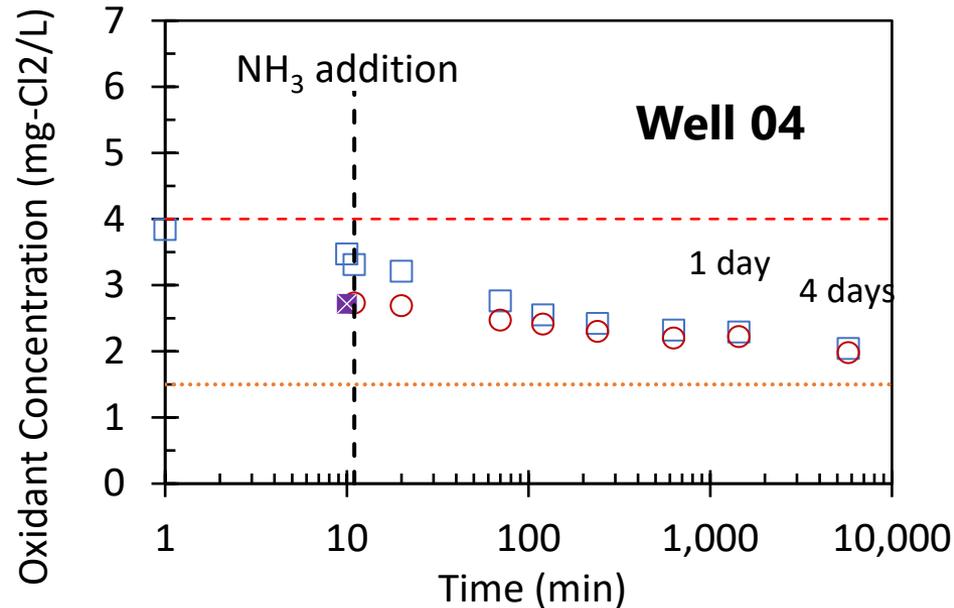

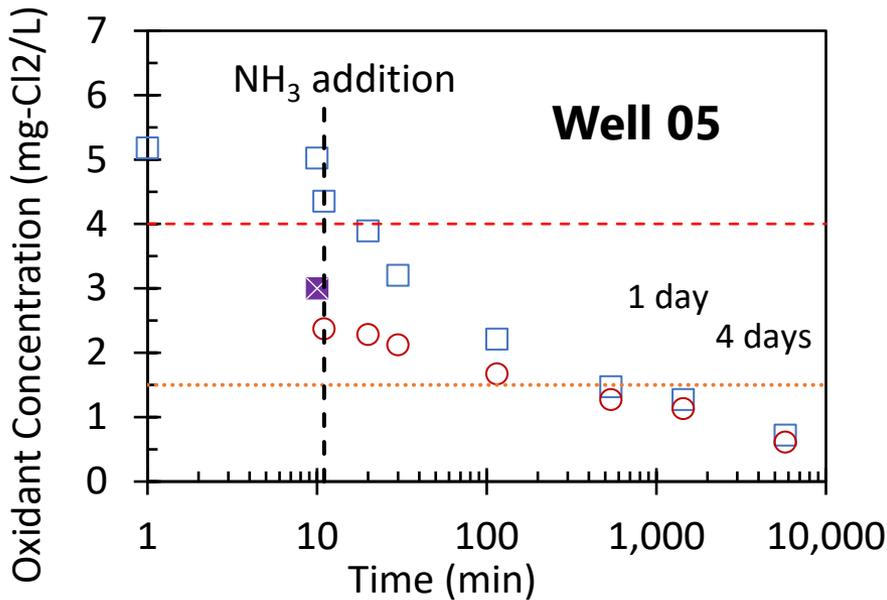

## Bromochloramine formation

Luh, J., & Mariñas, B. J. (2014). Kinetics of bromochloramine formation and decomposition. *Environmental science & technology*, 48(5), 2843-2852.

- Hach's total chlorine method detects both:
  - Non-brominated oxidants (e.g.,  $\text{HOCl}$ ,  $\text{NH}_2\text{Cl}$ )
  - Brominated oxidants (e.g.,  $\text{HOBr}$ ,  $\text{NH}_2\text{Br}$ ,  $\text{NHBrCl}$ )
- Brominated oxidants that, are relatively unstable, can appear to be unstable chlorine

# SDS testing results: chlorine detection methods

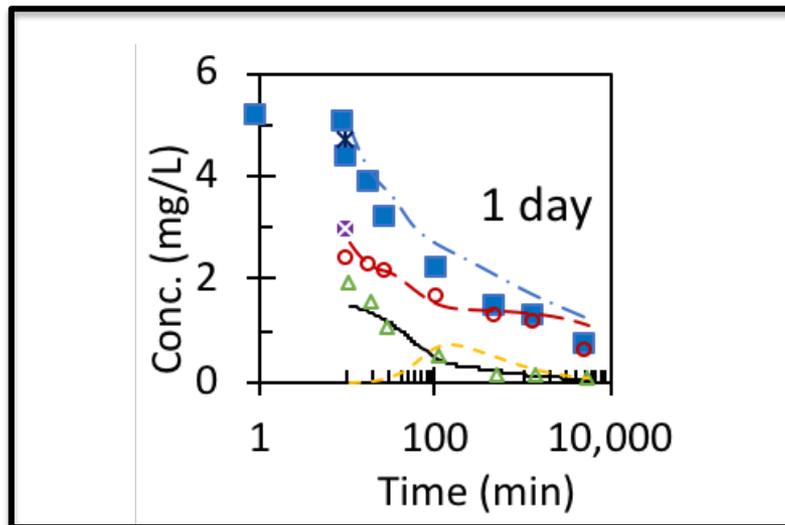

- Hach monochloramine method only detects monochloramine
  - Relies on indophenol (IP) chemistry
  - IP formation is highly specific to NH<sub>2</sub>Cl, does not experience interference from bromine containing oxidants
- Indophenol (IP) free chlorine method does not experience HOBr interference
- Difference in total chlorine and NH<sub>2</sub>Cl likely a result of brominated oxidants

# Modeling bromamine formation/decay

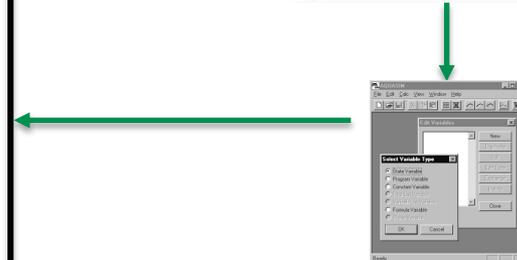

- To further validate bromide was the cause of chlorine decay, modeling was performed using
  - Reaction kinetics software AQUASIM
  - Chlorine, ammonia, and bromine reaction rate constants from Luh and Mariñas, 2014

Luh, J., & Mariñas, B. J. (2014). Kinetics of bromochloramine formation and decomposition. *Environmental science & technology*, 48(5), 2843-2852.

```
Table 1. Kinetic Rate Constants for Bromochloramine Formation and Decomposition (Luh and Mariñas, 2014)
```

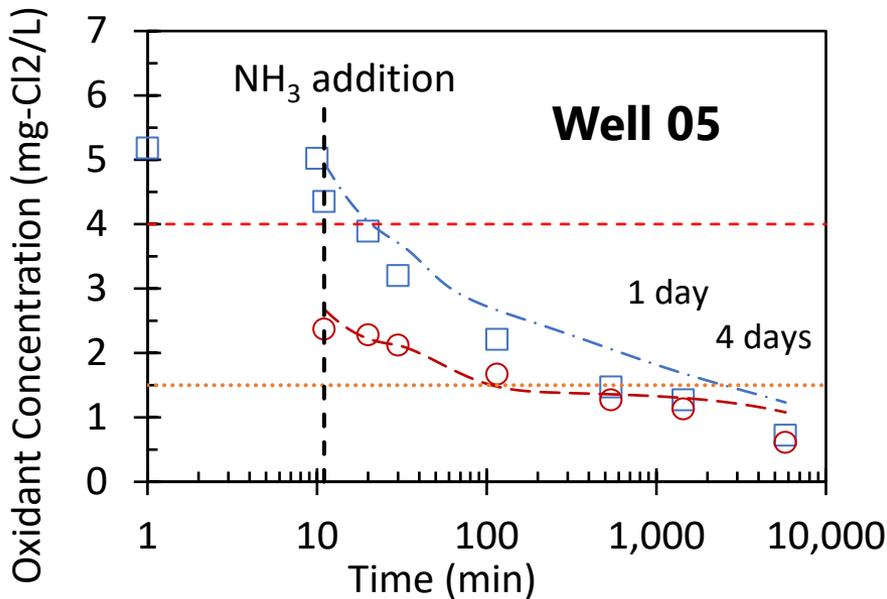

Reaction	Rate Constant (L/mol·min)
Cl <sub>2</sub> + H <sub>2</sub> O → HOCl + HOCl	1.0 × 10 <sup>10</sup>
HOCl + NH <sub>3</sub> → NH <sub>2</sub> Cl + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
HOCl + Br <sup>-</sup> → HOBr + Cl <sup>-</sup>	1.0 × 10 <sup>10</sup>
NH <sub>2</sub> Cl + HOCl → NHCl <sub>2</sub> + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NHCl <sub>2</sub> + HOCl → NCl <sub>3</sub> + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NH <sub>2</sub> Cl + HOBr → NH <sub>2</sub> Br + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NH <sub>2</sub> Br + HOCl → NHCl <sub>2</sub> + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NH <sub>2</sub> Br + HOBr → NBr <sub>2</sub> + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NHCl <sub>2</sub> + HOBr → NHClBr + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NHClBr + HOCl → NCl <sub>2</sub> + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NHClBr + HOBr → NBrCl + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NBr <sub>2</sub> + HOCl → NBrCl + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NBr <sub>2</sub> + HOBr → NBr <sub>2</sub> + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NCl <sub>2</sub> + HOCl → NCl <sub>2</sub> + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NCl <sub>2</sub> + HOBr → NClBr + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NBrCl + HOCl → NBrCl + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NBrCl + HOBr → NBrCl + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NClBr + HOCl → NClBr + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>
NClBr + HOBr → NClBr + OH <sup>-</sup>	1.0 × 10 <sup>10</sup>

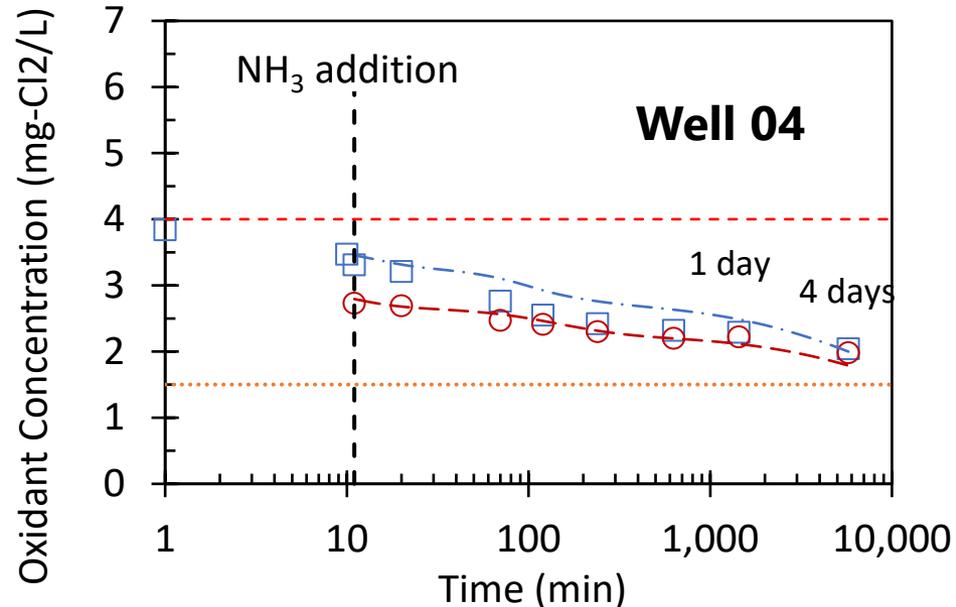

**AQUASIM**

# SDS testing results: modeling

□ Total Chlorine (Data)  
- - - Total Oxidant  
..... M56 Minimum Residual

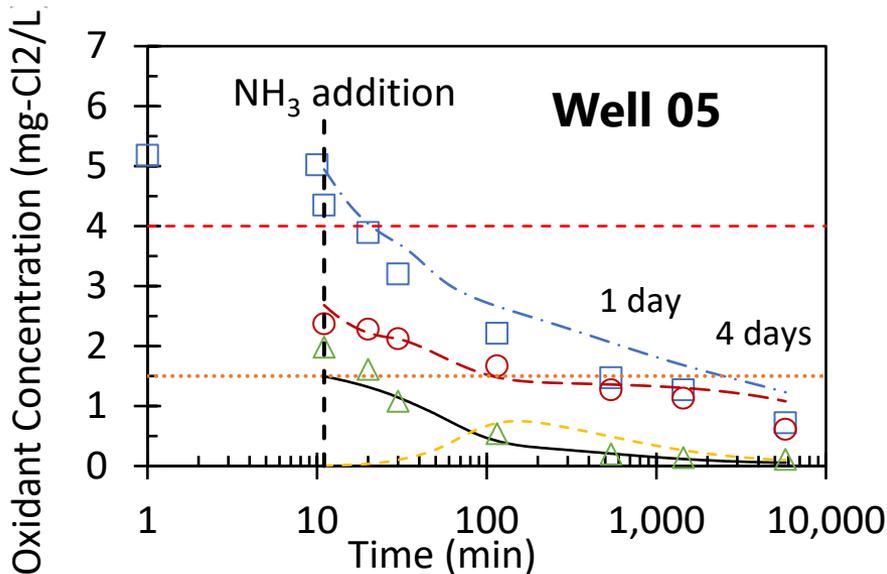

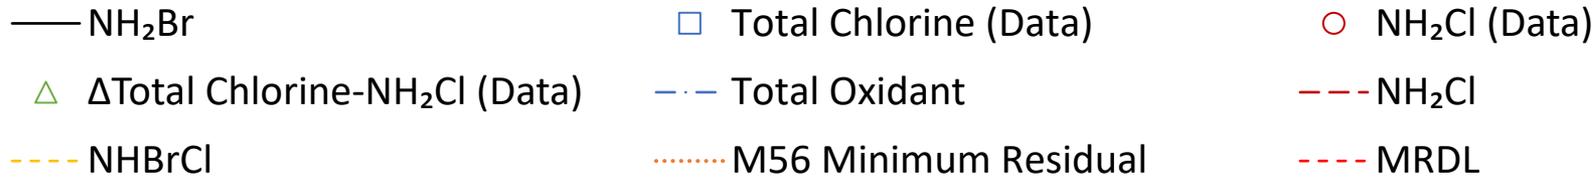

○ NH<sub>2</sub>Cl (Data)  
- - - NH<sub>2</sub>Cl  
- - - MRDL

- Lines = model simulations
  - Model accounts for the presence of bromamines & bromochloramine
- Bromamines are unstable
  - Decays mostly in a few hours
- Model assumes no TOC is present
  - Likely source of model deviations from data

# SDS testing results: chlorine detection methods

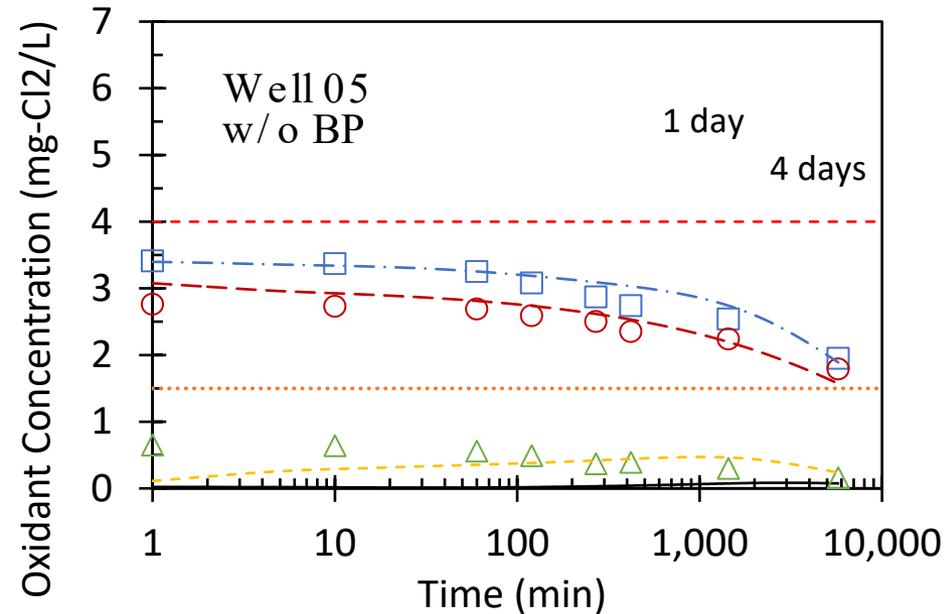

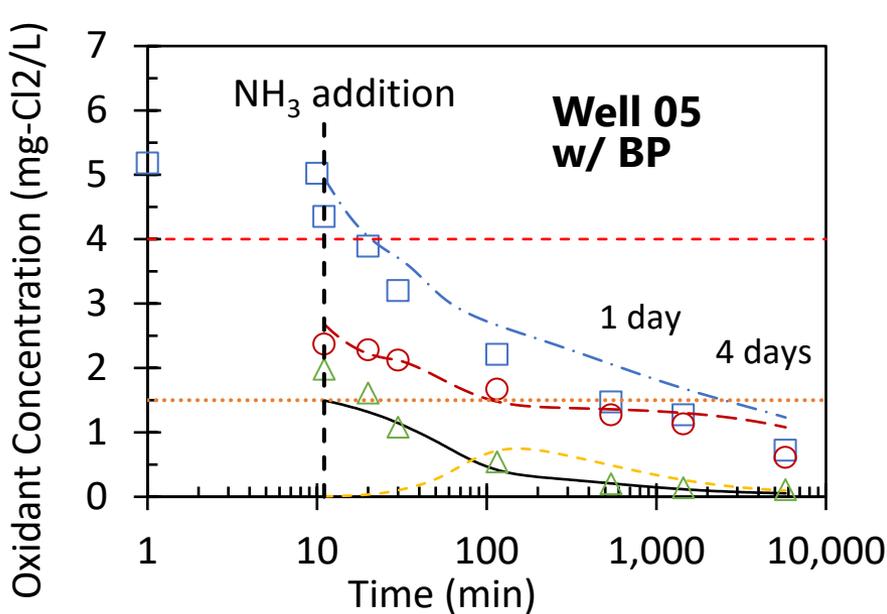

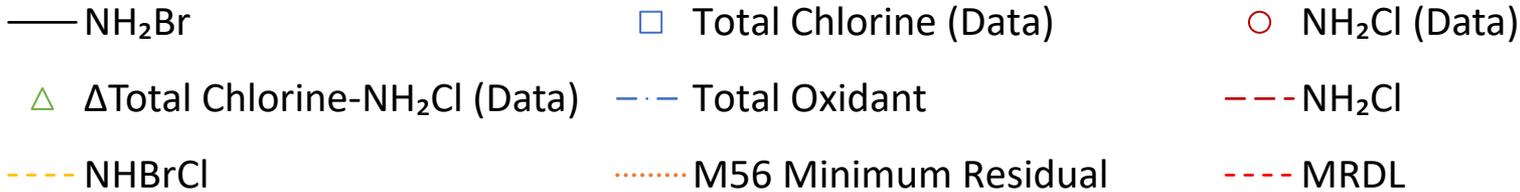

- Total chlorine - NH<sub>2</sub>Cl = brominated oxidants (e.g., NH<sub>2</sub>Br)
- More raw water bromide makes total chlorine measurement unstable because:
  1. Unstable NH<sub>2</sub>Br is formed instead of more stable NH<sub>2</sub>Cl

2. NH<sub>2</sub>Br attacks NH<sub>2</sub>Cl, making the NH<sub>2</sub>Cl that is present, less stable

# SDS testing results: chlorine detection methods

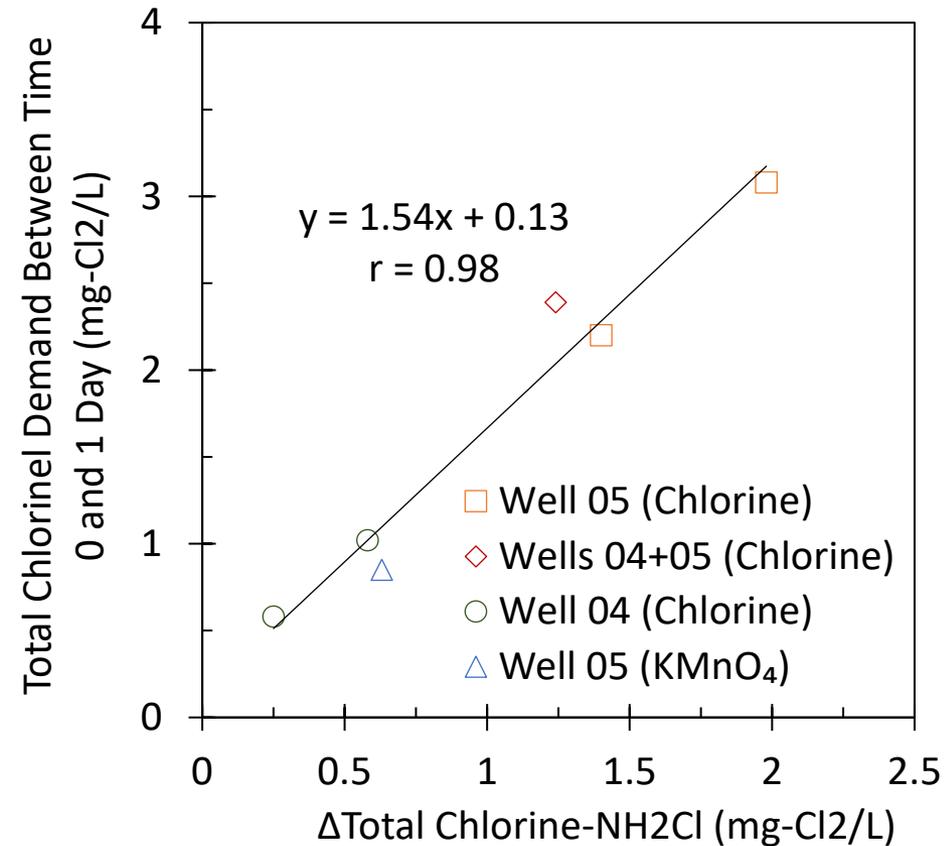

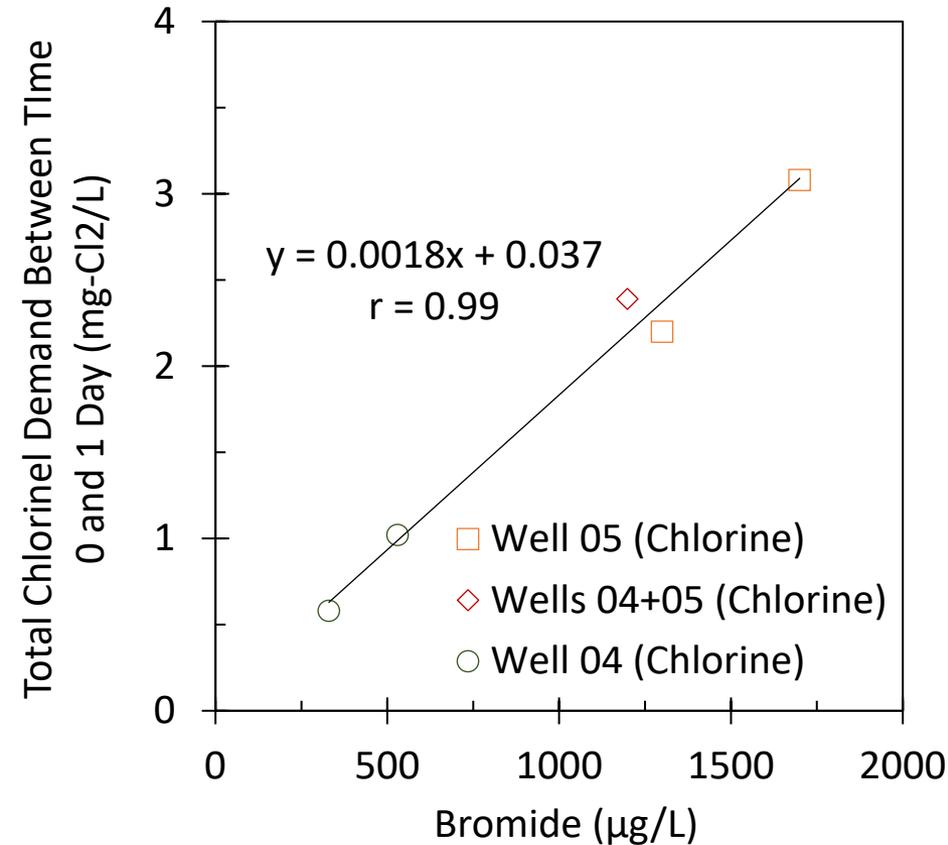

- Adding ammonia before chlorine to form chloramines makes total chlorine measurement more stable

- HOCl reacts faster with NH<sub>3</sub> relative to Br<sup>-</sup>

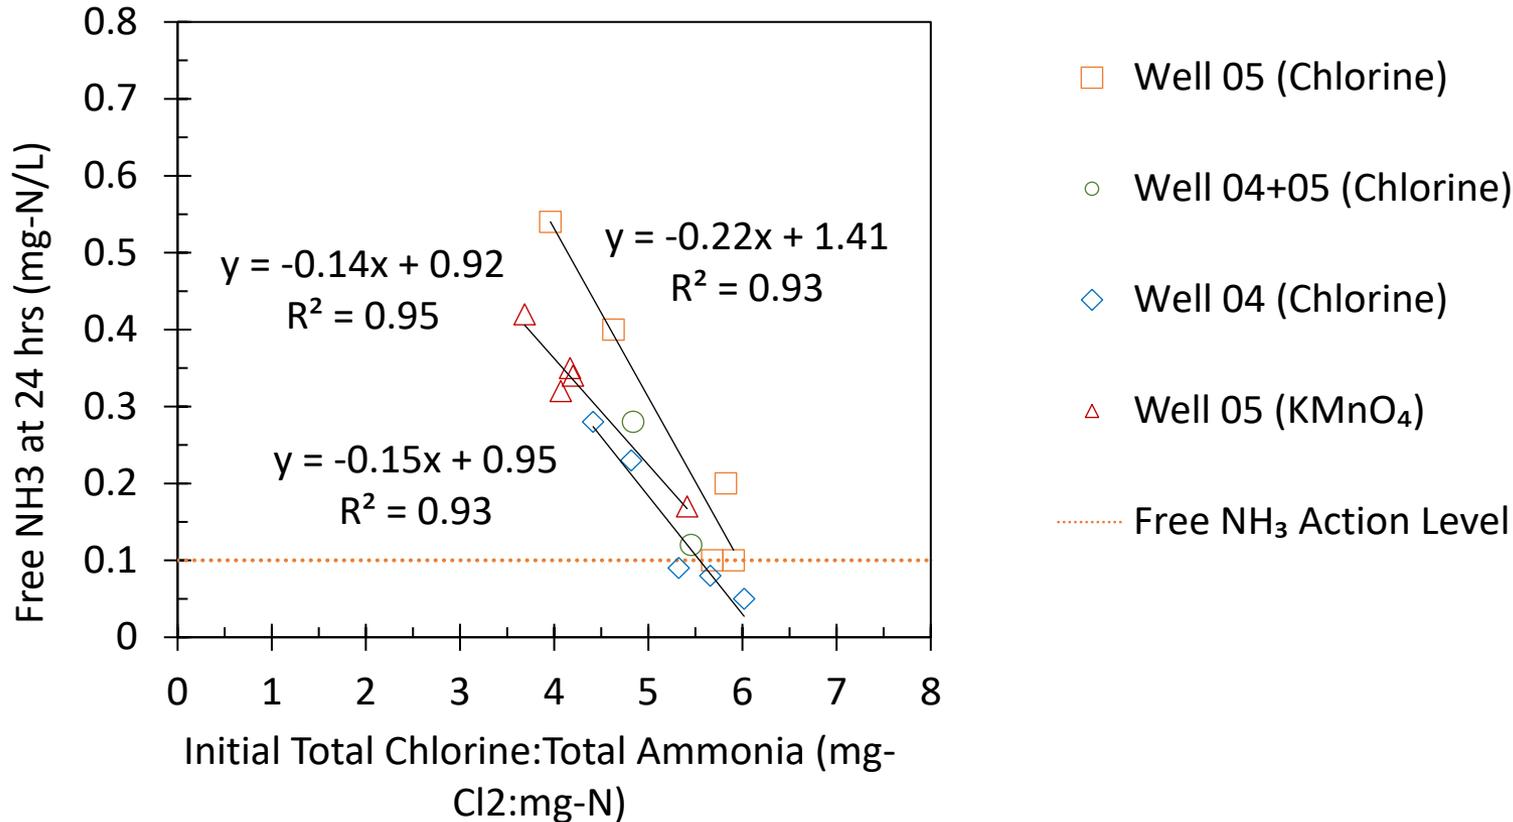

- Some bromamines will form, but much less (e.g.,  $\text{Br}^- + \text{NH}_2\text{Cl} \rightarrow \text{NH}_2\text{Br}$  is slow)

# SDS testing results: bromide vs chlorine demand

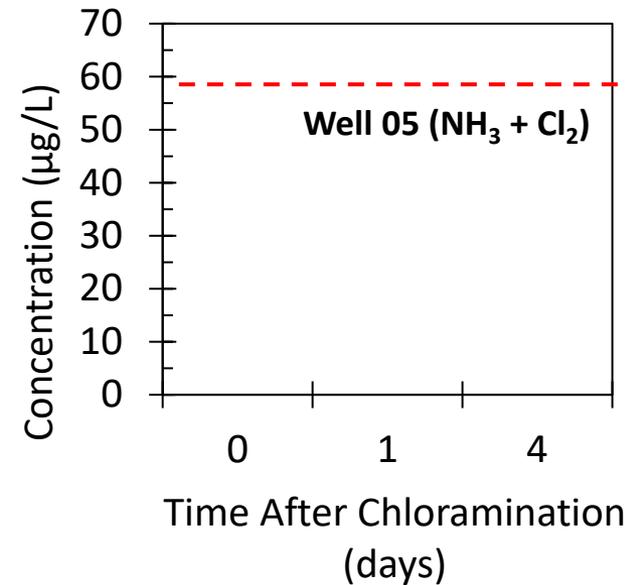

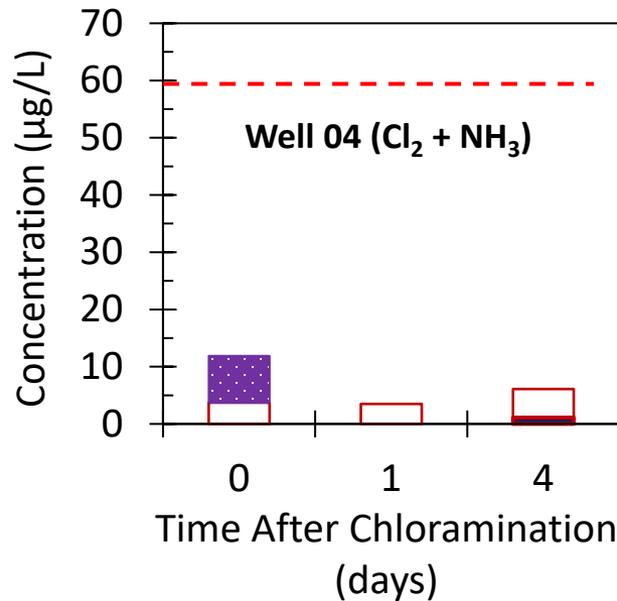

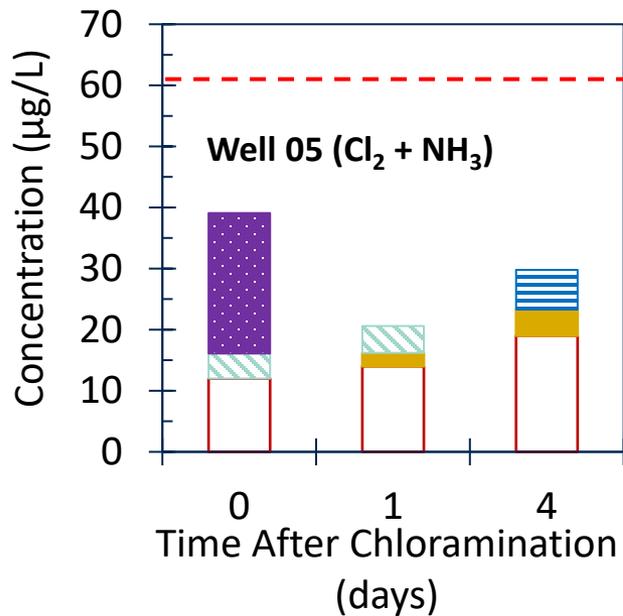

- Chlorine demand caused by bromide can be predicted based on:
  - Raw water bromide concentrations
  - Total chlorine - NH<sub>2</sub>Cl = brominated oxidant concentration measured right after chloramine formation

# SDS testing results: free ammonia

- Bromide also causes more free ammonia to be released
- High Cl:NH<sub>3</sub> ratios should be targeted:
  - Around 5:1
  - Higher than 5:1?

# SDS testing results: HAAs

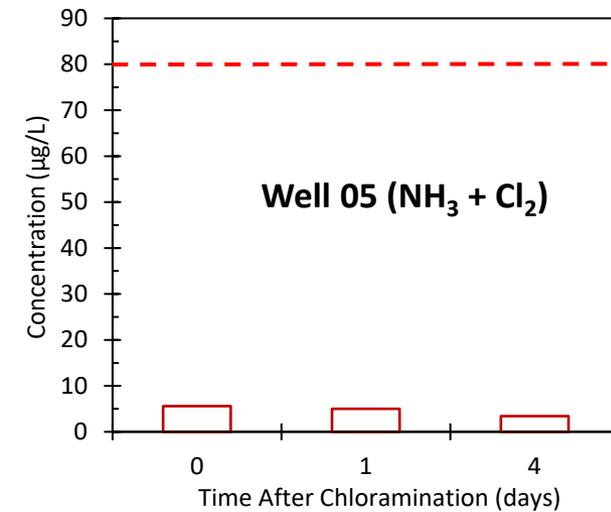

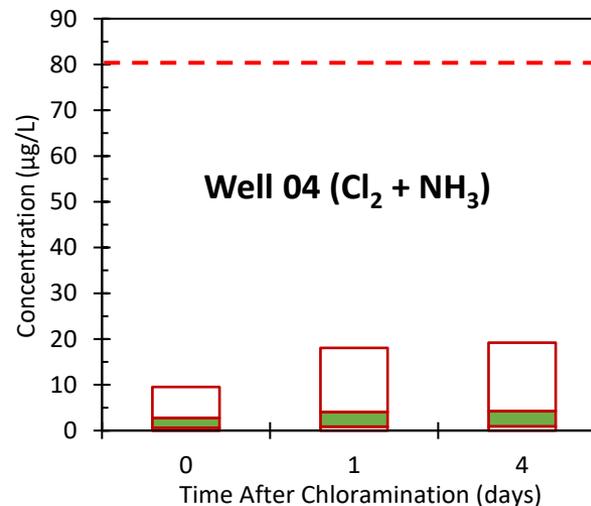

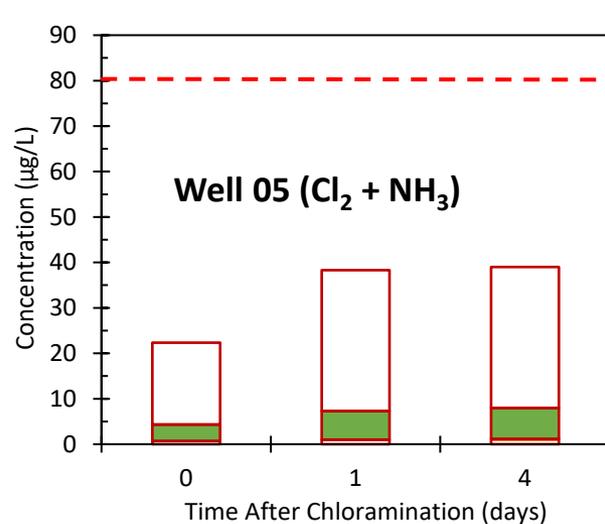

- More HAAs formed in high bromide water
- Adding  $\text{NH}_3$  before  $\text{Cl}_2$  inhibited HAA formation even in high bromide water

# SDS testing results: THMs

■ Bromodichloromethane  
□ Bromoform

■ Dibromochloromethane  
- - - MCL

- More THMs formed in high bromide water
- Adding  $\text{NH}_3$  before  $\text{Cl}_2$  limited THM formation in high bromide water

# Study Takeaways

- Bromide makes measured total chlorine unstable in chloraminated systems because:
  - Unstable brominated oxidants can form in place of  $\text{NH}_2\text{Cl}$
  - Hach's total chlorine method detects brominated oxidants
  - Brominated oxidants degrade  $\text{NH}_2\text{Cl}$

# Study Takeaways

- Brominated oxidant formation can be managed with simple process modifications, but planning is needed, e.g.,
  - Adding  $\text{NH}_3$  before  $\text{HOCl}$  to form chloramines
    - Adding  $\text{KMnO}_4$  to achieve Mn removal via greensand filtration allowed  $\text{NH}_3$  to be added first without forming brominated oxidants
  - Chlorine measurements may need reevaluation (total chlorine vs IP chlorine vs  $\text{NH}_2\text{Cl}$  measurements)
  - Greater free  $\text{NH}_3$  release and nitrification may be more of an issue

# Thank you!
